

PRODUCT DATA SHEET

Cerebrosides, bovine

Catalog No: 1050

Common Name: Galactosylceramide; Ceramide
beta-D-galactoside
(contains both hydroxy and non-
hydroxy fatty acid side chains)

Source: natural, bovine spinal cord

Solubility: chloroform/methanol (2:1); DMSO

CAS No: 85305-88-0

Molecular Formula: C₄₈H₉₃NO₉

Molecular Weight: 828 (2-hydroxytetracosanoyl)

Storage: -20°C

Purity: TLC > 98%; identity confirmed by MS

TLC System: chloroform/methanol/DI water
(80:20:1 by vol.)

Appearance: solid

Application Notes:

This cerebroside product is a glycosphingolipid containing a galactose (galactocerebroside) attached to a ceramide acylated with hydroxy and non-hydroxy fatty acids. Galactocerebrosides are found primarily in neuronal tissues and are the major glycosphingolipids in the central nervous system. They are the largest single component of the myelin sheath of nerves and seem to act, along with other molecules, to form part of the structural support of the myelin sheath.¹ Cerebrosides are involved in a very wide range of biological activities such as cell agglutination, intracellular communication, cellular development, and antitumor/cytotoxic effects.² Galactocerebroside can be metabolized into sulfatide which is also abundant in the nervous system and myelin sheaths. Due to the relatively high melting point of cerebrosides (much greater than physiological body temperature) they have a para-crystalline structure. Krabbe's disease (globoid cell leukodystrophy) is characterized by a deficiency in the enzyme galactocerebrosidase, which is responsible for degrading galactocerebroside. This leads to an accumulation of cerebroside and psychosine (which is very cytotoxic and can result in demyelination of nerves and loss of axonal conductivity). This standard from Matreya is excellent for use in the identification and isolation of cerebrosides in the study of Krabbe's disease and other studies.³
